Description

[KAmoDRPi5 PCIe-M.2 mini](#) - Miniature NVME M.2 M-Key Disk Adapter for Raspberry Pi 5

The Raspberry Pi 5 computer is equipped with a PCI Express interface led out to a custom, miniature FFC connector marked on the board as PCIe. It allows you to connect modern SSDs that support the fast and reliable NVME protocol, and then the Raspberry Pi can become a multimedia center or file server, while maintaining a small size and energy efficiency. This requires the use of the KAmoDRPi5 M.2 mini adapter, which allows you to connect an NVME disk with an M.2 M-key connector, in size **2230** or **2242**.

Basic parameters

- The adapter is designed for easy installation on the Raspberry Pi 5 board
- The connection to the Raspberry Pi 5 computer is via a 16/0.5 FFC ribbon
- It does not block the 40-pin GPIO connector
- It allows you to connect an NVME drive with an M.2 M-key (NGFF M-key) connector
- Communication via the PCI Express Gen2 x1 interface (optionally also Gen3 x1)
- It allows you to mount a 2230 or 2242 size drive
- It supplies a voltage of 3.3 V and a maximum current of 1 A to power the drive
- LED indicators signaling correct power supply and drive activity
- Dimensions: 32.5x64 mm
- The design of the adapter does not block the possibility of using a dedicated radiator with a fan for Raspberry Pi 5 - Raspberry Pi Active Cooler

Not every NVME M.2 drive is compatible with the Raspberry Pi 5 computer

Standard equipment

Code	Description
KAmoD RPi5 M.2 mini	Assembled and started module
FFC 16/0.5 tape	Makes electrical connection of PCI Express interface
Mounting kit:	Allows to mount the adapter on the RPi5 board
• Spacer - 2 pcs.	
• M2 screw - 4 pcs.	
• M.2 disk mounting clip	

PCI Express connector

Connector	Description
J1 - RPi5 PCIe	<ul style="list-style-type: none"> Connects the PCIe interface on the Raspberry Pi 5 board to the KAmoD RPi5 M.2 mini adapter Responsible for data transfer, but also supplies power to the adapter

The PCI Express connector of the KAmoD RPi5 M.2 mini adapter should be connected to the PCIe connector on the Raspberry Pi 5 board using an FFC 16/0.5 connecting ribbon. The ribbon should be inserted from the edge of the board, with the contacts aligned to the board plane - i.e. the blue marker must be on the outside, as shown in the figure below. Before inserting the ribbon into the connector, gently push back the lock on the J1 connector (dark element) - by approx. 2 mm. After inserting the ribbon, the lock should be gently pushed in so that the ribbon is locked in the connector.

NVME M.2 M-key Drive Connector

Connector	Description
J2 - M.2 M-KEY	<ul style="list-style-type: none"> Allows you to connect an NVME drive with an M.2 connector, with the so-called with an “M” type key (M-KEY) Provides a 3.3V drive power supply with a maximum current of 1A Connects an NVME M.2 drive with a PCI Express Gen2 x1 interface

The J2 type M.2 (NGFF) connector with an “M” type key (M-KEY) allows you to connect a standard NVME drive. The set of holes on the board allows for stable mounting of drives in sizes 2230 or 2242.

2230	✓
2242	✓
2260	✗
2280	✗
22110	✗

LED indicator lights

LED indicator light	Description
D1 - STATUS	When the light is on, it indicates that data is being written/read/transferred to the NVME drive
D2 - POWER	A clear glow indicates correct power parameters of the NVME drive

Mounting the NVME M.2 drive in the KAmoD RPi5 M.2 mini adapter

Note! Connecting and disconnecting the NVME M.2 drive should only be done when the Raspberry Pi 5 computer is turned off and disconnected from the power supply.

First, determine the size of the drive (not the capacity) - **2230** or **2242** drives are accepted. Knowing the size of the drive, install the flexible mounting clip in the hole corresponding to the given size of the drive. Now you can insert the NVME M.2 drive into the J2 connector (M.2 M-KEY), so that the end of the drive protrudes slightly from the board. Then, gently tilt the mounting clip towards the edge of the board, press the drive against the clip and release the clip so that it locks the drive in the adapter.

Mounting the KAmoD RPi5 M.2 mini adapter on the Raspberry Pi 5 board

First, connect the FFC ribbon to the RPi5 PCIe connector, from the edge of the board, with the contacts aligned to the board plane - i.e. the blue marker must be on the outside, as shown in the drawing in the chapter [PCI Express connector](#). Before inserting the ribbon into the connector, gently push back the lock on the J1 connector (dark element) - by about 2 mm. After inserting the ribbon, gently push in the lock so that the ribbon is locked in the connector.

Now, the KAmoD RPi5 M.2 mini adapter with the ribbon installed should be placed next to the Raspberry Pi 5. This allows you to easily connect the FFC ribbon to the PCIe connector on the Raspberry Pi 5 board. Here, too, you should slide out the lock, place the ribbon with the contacts toward the center of the board, and push in the lock so that the ribbon is locked in the connector.

After attaching the ribbon, place the adapter above the Raspberry Pi 5 computer and arrange the ribbon so that it is between the boards (or between the adapter board and the RPi5 radiator). Finally, you should install 16 mm high sleeves at the GPIO connector, which will hold the entire structure stably.

Dimensions of the KAmoD RPi5 M.2 mini adapter

The dimensions of the board are 32.5x64 mm, its shape does not block access to the GPIO connector and other connectors on the RPi 5 board.

Booting the system from an NVME M.2 drive

Booting the Raspberry Pi 5 system from an NVME drive requires installing a system image on that drive. This can be done by having an RPi5 computer running from a microSD memory card. The following steps should be performed:

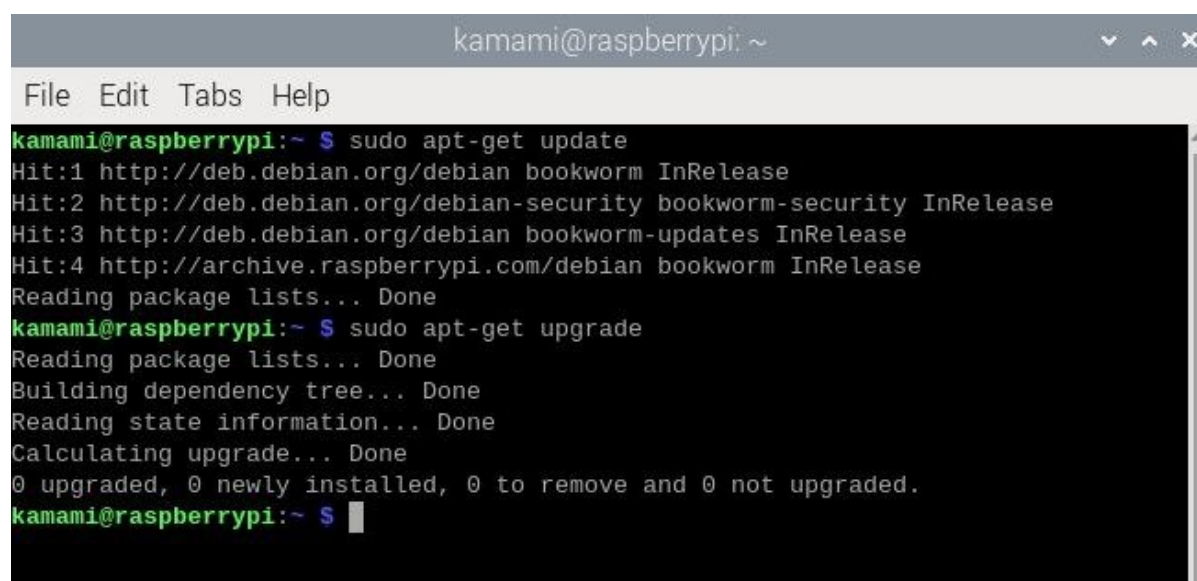

Operating system update

We start RPi5 with a mounted memory card containing the working Raspberry Pi 5 operating system. After the system desktop is displayed, open the console window (Terminal), e.g. using the key combination *Ctrl+Alt+T* and enter:

```
sudo apt-get update
```

and then:

```
sudo apt-get upgrade
```

A screenshot of a terminal window titled 'kamami@raspberrypi: ~'. The window has a menu bar with 'File', 'Edit', 'Tabs', and 'Help'. The terminal output shows the execution of two commands. The first command is 'sudo apt-get update', which outputs four 'Hit' messages for different sources and 'Reading package lists... Done'. The second command is 'sudo apt-get upgrade', which outputs 'Reading package lists... Done', 'Building dependency tree... Done', 'Reading state information... Done', 'Calculating upgrade... Done', and '0 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.' The prompt 'kamami@raspberrypi:~ \$' is visible at the end of the output.

```
kamami@raspberrypi:~ $ sudo apt-get update
Hit:1 http://deb.debian.org/debian bookworm InRelease
Hit:2 http://deb.debian.org/debian-security bookworm-security InRelease
Hit:3 http://deb.debian.org/debian bookworm-updates InRelease
Hit:4 http://archive.raspberrypi.com/debian bookworm InRelease
Reading package lists... Done
kamami@raspberrypi:~ $ sudo apt-get upgrade
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Calculating upgrade... Done
0 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.
kamami@raspberrypi:~ $
```

Completing all the actions may take several minutes, depending on the number of components that require updating (the console window may display many more messages than in the example below). Any questions should be confirmed by pressing Y (Yes).

Finally, restart the system, e.g. by entering the command:

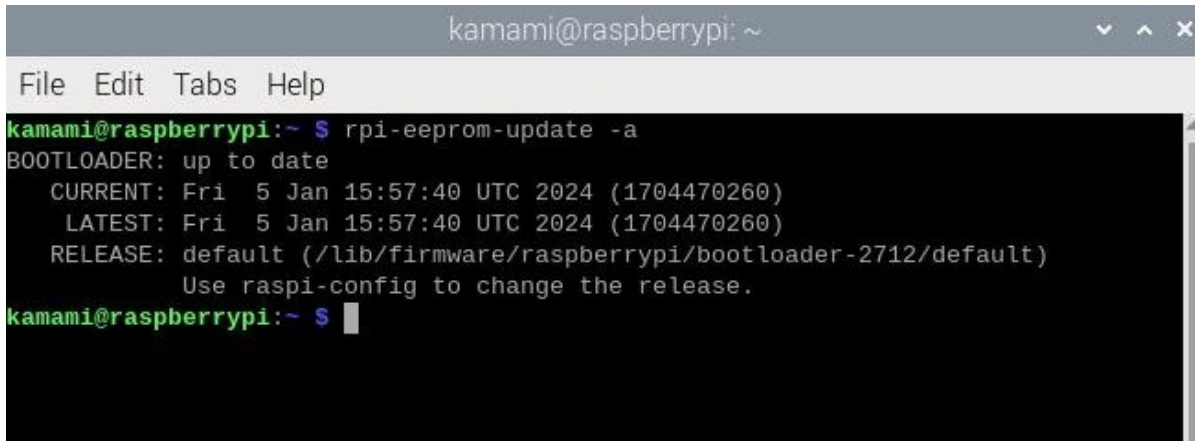

```
sudo reboot
```

Updating the EEPROM memory content

Open the console window (Terminal), e.g. by pressing Ctrl+Alt+T and entering:

```
sudo rpi-eeeprom-update -a
```

The console window may display more messages than in the example below if the content requires updating. Any questions should be confirmed by pressing Y (Yes).

A screenshot of a terminal window titled 'kamami@raspberrypi: ~'. The window has a menu bar with 'File', 'Edit', 'Tabs', and 'Help'. The terminal shows the command 'rpi-eeeprom-update -a' being executed. The output is as follows:

```
kamami@raspberrypi:~ $ rpi-eeeprom-update -a
BOOTLOADER: up to date
CURRENT: Fri 5 Jan 15:57:40 UTC 2024 (1704470260)
LATEST: Fri 5 Jan 15:57:40 UTC 2024 (1704470260)
RELEASE: default (/lib/firmware/raspberrypi/bootloader-2712/default)
        Use raspi-config to change the release.
kamami@raspberrypi:~ $
```

After completing the actions, it is necessary to restart the system, which we can invoke, for example, by entering the command:

```
sudo reboot
```

Installing the system on the NVME M.2 drive

With the RPi5 turned off, we mount the KAmoD RPi5 M.2 mini adapter with the mounted NVME M.2 drive. We start Raspberry Pi 5, open the console window (Terminal), e.g. using the Ctrl+Alt+T key combination, and enter:

```
sudo rpi-imager
```

In the window that appears, select:

- computer model (Raspberry Pi Device): **RASPBERRY PI 5**,
- operating system (Operating System): **RASPBERRY PI OS (64-BIT)**,
- disk (Storage): here we indicate the NVME M.2 disk, which was mounted in the KAmoD RPi5 M.2 mini adapter.

The further steps of installing the operating system image can be found in the official Raspberry Pi documentation:

<https://www.raspberrypi.com/documentation/computers/getting-started.html>

Finally, turn off the RPi5.

Starting the system

When we have an NVME M.2 drive mounted with the installed operating system image, before starting the Raspberry Pi 5 computer, remove the memory card from the dedicated slot - it will no longer be needed (the memory card can be removed/mounted only when the computer is turned off and disconnected from the power supply).

The first boot of the new operating system will take a little longer than the next ones, but after a while you will see the desktop of a ready-to-work Raspbian installed on the NVME M.2 drive. This is a new operating system and does not contain the changes we made to the system on the memory card. Therefore, we need to perform an operating system update, as described earlier. We do not need to update the EEPROM content - it did not change after the change of the operating system.

Increasing the speed of the PCIe interface

The PCIe interface of the Raspberry Pi 5 computer starts by default in gen 2 mode, which allows communication with a maximum throughput of 5 GT/s (Gigatransfers per second). There is a way to start gen 3 mode, which offers a throughput of up to 8 GT/s. To do this, modify the contents of the configuration file *config.txt*.

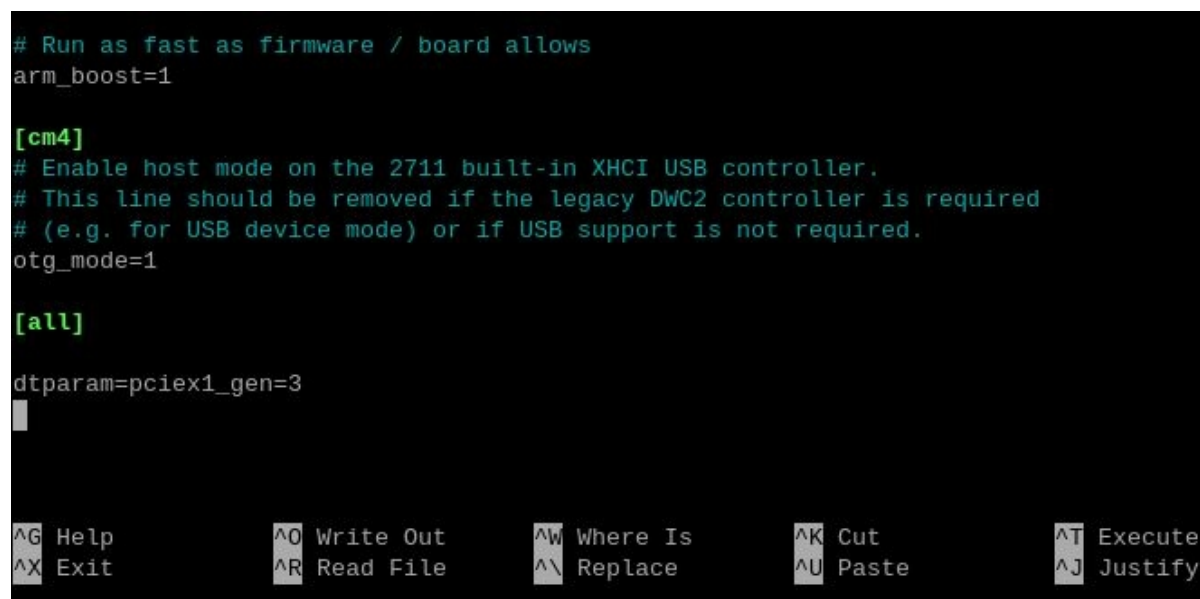

In the console, type:

```
sudo nano /boot/firmware/config.txt
```

(in earlier versions of the operating system, the file *config.txt* was placed directly in the */boot* directory).

At the end of the file (scroll to the bottom with the arrows), add the line:

```
dtparam=pciex1_gen=3
```

```
# Run as fast as firmware / board allows
arm_boost=1

[cm4]
# Enable host mode on the 2711 built-in XHCI USB controller.
# This line should be removed if the legacy DWC2 controller is required
# (e.g. for USB device mode) or if USB support is not required.
otg_mode=1

[all]

dtparam=pciex1_gen=3

```

Then, save the changes using the *Ctrl+O* keys, close the editor using the *Ctrl+X* keys, and restart the system.

To check if the modification worked, you can analyze the system boot messages. Open the console window (Terminal), e.g. using the key combination *Ctrl+Alt+T* and enter:

```
dmesg | grep pcie
```

You will see content similar to the one in the screenshot below:

File Edit Tabs Help

```

kamami@raspberrypi:~$ dmesg | grep pcie
[ 0.000000] Kernel command line: reboot=w coherent_pool=1M 8250.nr_ua
000000 console=ttyAMA10,115200 console=tty1 root=PARTUUID=c0b784bf-02
0.393754] brcm-pcie 1000110000.pcie: host bridge /axi/pcie@110000 ranges:
[ 0.393762] brcm-pcie 1000110000.pcie: No bus range found for /axi/pcie@110000, using [bus 00-ff]
[ 0.393773] brcm-pcie 1000110000.pcie: MEM 0x1b00000000..0x1bfffffffb -> 0x0000000000
[ 0.393779] brcm-pcie 1000110000.pcie: MEM 0x1800000000..0x1affffffff -> 0x0400000000
[ 0.393785] brcm-pcie 1000110000.pcie: IB MEM 0x0000000000..0xffffffff -> 0x1000000000
[ 0.394961] brcm-pcie 1000110000.pcie: setting SCB_ACCESS_EN, READ_UR_MODE, MAX_BURST_SIZE
[ 0.394967] brcm-pcie 1000110000.pcie: Forcing gen 3
[ 0.395004] brcm-pcie 1000110000.pcie: PCI host bridge to bus 0000:00
[ 0.503759] brcm-pcie 1000110000.pcie: link up, 8.0 GT/s PCIe x1 (!SSC)
[ 0.515879] pcieport 0000:00:00.0: enabling device (0000 -> 0002)
[ 0.515917] pcieport 0000:00:00.0: PME: Signaling with IRQ 39
[ 0.515980] pcieport 0000:00:00.0: AER: enabled with IRQ 39

```

You can see the entries: "*Forcing gen 3*" and "*Link up, 8.0 GT/s PCIe x1*", which means that the modification was successful. **However, this does not guarantee full system stability under all conditions.**
